Background

- While there is evidence that physical activity (PA) can improve cognition and prevent cognitive decline, our understanding of the mechanisms through which PA exerts these effects remains unclear¹
- Two recently proposed mechanisms which warrant further investigation are cerebral blood flow (CBF) and sleep efficiency².

Objectives

- To examine relationships between PA, sleep efficiency, CBF and cognitive ability in a sample of sedentary non-demented older adults
- To investigate sleep efficiency and global gray matter CBF as potential mediators of the relationship between PA and cognitive ability

Methods

Study Demographics		Measures
N	47	Physical Activity and Sleep Efficiency
M/F	15/32	• Physical activity and sleep efficiency were measured using GENEActiv accelerometer which participants wore 24 hou days preceding their in-person visit. Measures were average
Age	66.45 (6.79)	• Physical activity measures were categorized by gravitationa units into light (30–100 mg) and moderate to vigorous PA (
Edu	16.49 (2.47)	 mg) Sleep efficiency = time asleep / time in bed.
ApoE+/ ApoE-	13/34	 Cerebral Blood Flow Global gray matter CBF was quantified using a pseudo-con arterial spin labeling MRI scan
MoCA	26.13 (2.36)	 Neuropsychological Measures The Montreal Cognitive Assessment (MoCA), Flanker Tasl
CVLT	21.89 (6.21)	congruent and incongruent trials – lower scores indicate be performance), and California Verbal Learning Test (CVLT)
Flanker	1.23 (.10)	long delay free recall) were used to assess cognitive ability Statistical Analyses
Light PA	479.54 (243.66)	• Linear regression analyses adjusting for age, sex, education status were conducted to examine the relationships between
MVPA	31.77 (32.53)	efficiency, CBF, and cognitive ability.Indirect effects of PA on cognitive ability were assessed us
Sleep Efficiency	.73 (.05)	 lavaan Exploratory analyses examined the role of gender in relation between PA, sleep efficiency, CBF, and cognitive ability

Results

- Sleep efficiency and global gray matter CBF are significantly related to global cognition • No significant relationships between PA and cognition or between PA and sleep efficiency were
- observed. Relationships between PA and CBF were significantly related only in women. • Cerebral blood flow was not a significant mediator of the relationship between PA and cognition.
- A. Sleep Efficiency ~ Physical Activity

	Light PA	MVPA	
Sleep Efficiency	β =2.76e ⁻⁰⁵ , p = .42	$\beta = 8.17e^{-05},$ p = .77	

C. CBF ~ Physical Activity

CBF ~ Physical Activity			D.	D. Cognitive Abi	
	Light PA	MVPA			
CBF	β=0.01,	β=0.01,		CBF	β=
	p = .11	$\mathbf{p} = .82$			p <

Table 1: Significant relationships are shown in bold. Models were adjusted for age, sex, education and ApoE status. MoCA = Montreal Cognitive Assessment total score; CVLT = California Verbal Learning Test short and long delay free recall; Flanker = Difference in reaction time for congruent and incongruent trials. Lower scores indicate better performance.

Higher sleep efficiency is associated with increased global gray matter CBF

predictive of gray matter CBF across all subjects (p < .05)

Discussion

Conclusions

- The effect of light levels of physical activity on cerebral blood flow differs based on gender
- Cerebral blood flow and sleep efficiency may interact to influence cognitive ability, rather than through separate mechanisms

Future Directions

- Analyze day-to-day patterns of physical activity and sleep efficiency using time series analysis, and investigate how these patterns influence cognition and CBF.
- Investigate relationships between PA, sleep efficiency, cognition, and **ROI specific** CBF. Lab website: thepalab.com Email: lefenton@usc.edu
